then we expect to find zeros in a neighborhood of each point of

$$w - w^{d+1}(f'(w))^{-1}Q(w).$$

The set $Q(w)$ is connected [1], and for $w \notin \mathbf{R}$, it seems that it contains a small disk around the origin. The set $Q(w)$ is a continuous function of w , which accounts for the similarity of the protrusions from \bar{W} visible in Figures 5 and 6. (The protrusions in Figure 4 are different, since there the sets $Q(w)$ are of different shape from those in Figures 5 and 6.)

Acknowledgements. The authors thank E.R. Rodemich for originally raising the question of the distribution of zeros of 0, 1 polynomials, M. Sambandham for providing a copy of [15], A.R. Wilks for help with graphics, and D. Zagier for informing them of the work of T. Bousch [5, 6]. Special thanks are due to David desJardins and Emanuel Knill for permission to use their proofs of Lemma 5.1.
